PINCH MOVES AND THE NONORIENTABLE FOUR-GENUS OF KNOTS WITH AT MOST THIRTEEN CROSSINGS

DEEP BHATTACHARJEE

ABSTRACT. The smooth nonorientable four-genus $\gamma_4(K)$ of a knot is the least first Betti number of a smooth nonorientable surface in B^4 bounded by K. KnotInfo leaves it undetermined for 3525 prime knots with eleven to thirteen crossings. We determine it for 2093 of them and lower the known upper bound for 575 more. Each result comes from one pinch move, the nonorientable band move at a crossing of a diagram, that turns the knot into a slice knot or into a knot whose nonorientable four-genus is known. Every certificate is a diagram, a crossing and a target knot. A program independent of the search checks each one by Reidemeister moves or by an isomorphism of triangulated knot complements.

1. INTRODUCTION

Every knot $K \subset S^3 = \partial B^4$ bounds a smooth surface in B^4; if K is not slice, it bounds nonorientable ones as well. The *nonorientable four-genus* $\gamma_4(K)$ is the least first Betti number of a smooth compact nonorientable surface $F \subset B^4$ with $\partial F = K$; for slice knots one sets $\gamma_4(K) = 1$. It was studied by Murakami and Yasuhara [9] and by Gilmer and Livingston [4]. Its values on small knots were computed by Jabuka and Kelly for eight and nine crossings [6], by Ghanbarian for ten [3] and by Fairchild for nonalternating knots with eleven [2]. Lee and Sabloff [8] extended the computation to fourteen crossings with an algorithmic search for Möbius bands in the style of Dunfield and Gong [1], together with the Arf invariant obstruction of Yasuhara [12] and a linking form obstruction of Murakami and Yasuhara [9]. The KnotInfo database [7] incorporates these data. In its version 2026.10.5, 3525 knots with eleven to thirteen crossings have an interval $[a, b]$ with $a < b$ as the entry for γ_4.

Theorem 1. *For each of the 2093 knots listed in the data file* `certificates.json` *with the flag* `closed`*, $\gamma_4(K)$ equals the lower end of its KnotInfo interval: 465 knots have $\gamma_4(K) = 1$ and 1628 have $\gamma_4(K) = 2$. For the other 575 knots of the file the upper bound is lowered by at least one.*

Table 1 gives the counts by crossing number and by KnotInfo interval. The proof uses one elementary move.

Definition 2. Let D be a diagram of a knot K and c a crossing of D. Of the two smoothings of c, one respects the orientation of K and gives a two-component link; the other gives a knot K'. We say K' is obtained from K by a *pinch move* at c.

Lemma 3. *If K' is obtained from K by a pinch move, then $\gamma_4(K) \leq 1$ when K' is slice, and $\gamma_4(K) \leq \gamma_4(K') + 1$ in general.*

Proof. The pinch move is a band move, so there is a cobordism $\Sigma \subset S^3 \times [0, 1]$ from K to K' formed by $K \times [0, 1]$ and one band. Since K' is connected, the band does not respect the orientation of K, and Σ is a Möbius band with an open disk removed. If K' bounds a disk Δ in B^4, then $\Sigma \cup \Delta$ is a Möbius band bounded by K, so $\gamma_4(K) \leq 1$. If K' bounds a surface F with

Date: October 21, 2026.

$b_1(F) = \gamma_4(K')$, then $\Sigma \cup F$ is a nonorientable surface bounded by K with $b_1 = b_1(F) + 1$. This is the bound used by Jabuka and Kelly [6]. □

The lower bounds are not ours. A knot that is not slice has $\gamma_4 \geq 1$. For the knots whose interval starts at 2, the lower bound is the obstruction to bounding a Möbius band recorded by KnotInfo from Lee and Sabloff [8]: either Yasuhara's condition $4\,\mathrm{Arf}(K) - \sigma(K) \in \{0, \pm 2\}$ (mod 8) fails [12], or the linking form obstruction of Murakami and Yasuhara [9] applies. Theorem 1 therefore rests on these published obstructions, on the slice status and four-genus values recorded in KnotInfo for the targets, and on the certificates below.

2. Certificates and their verification

A certificate for a knot K consists of a planar diagram code D, a crossing c of D, a choice of smoothing, and a target: either the unknot or a knot T of KnotInfo. It asserts that

(1) D is a diagram of K;
(2) the chosen smoothing of c gives a one-component diagram D';
(3) D' represents T or its mirror image;
(4) the bound $\beta = 1$ if T is slice or the unknot, and $\beta = \gamma_4(T) + 1$ otherwise, is smaller than the upper end of the KnotInfo interval of K.

Since γ_4 and sliceness are invariant under mirror image, (1) to (4) and Lemma 3 give $\gamma_4(K) \leq \beta$.

The certificates were found with SnapPy [11]: for every open knot we applied every pinch move to the KnotInfo diagram and to up to twenty-five diagrams obtained from it by random Reidemeister moves, and identified the resulting knots by hyperbolic structure. A candidate enters the file only if the verifier below accepts it; when it did not, the search went on with other crossings and other diagrams of the same knot. A second pass used the knots settled in the first pass as targets; the number of certificates with such a target is 3, and the verifier checks them after the certificates of their targets.

The verifier `verify.py` does not use SnapPy. It reads the KnotInfo database and uses Regina [10] for the topology. For (1) and (3) it proves that two diagrams represent the same knot up to mirror image in one of two ways.

- *Isotopy.* Both diagrams are simplified by Reidemeister moves to the same number of crossings, and the closures of the two minimal diagrams under Reidemeister moves that add at most one crossing share a diagram. Diagrams are compared by Regina's canonical signatures, taken up to reflection, rotation and reversal.
- *Complements.* The triangulated complements of the two diagrams have combinatorially isomorphic triangulations, possibly after Pachner moves that add at most one tetrahedron, or one of the triangulations obtained from forty simplifications of each complement under fixed seeds of Regina's random engine, together with the triangulations one Pachner move away from the smallest of them, occurs for both diagrams. Each of these triangulations is a triangulation of the complement it came from, so a common one shows that the complements are homeomorphic, and by the theorem of Gordon and Luecke [5] the knots agree up to mirror image.

Both tests are exact: a positive answer is a proof. Regina's simplification is randomised, so the verifier makes up to four attempts, each from a fixed seed, and gives each certificate two minutes. For the unknot the verifier uses Regina's recognition of the solid torus. Item (2) is checked by following the strands of D', and (4) by reading KnotInfo.

The verifier accepts all 2668 certificates. It rejects certificates corrupted in four ways, on a sample of twenty: the other smoothing of the crossing, the next crossing, a wrong target, and a

bound lowered by one (Table 2). The seven modified certificates with the next crossing that it accepts are valid certificates: that crossing gives the same target.

3. Results

crossings	KnotInfo	knots	settled	lowered	open
11	[1, 2]	14	0	0	14
11	[1, 3]	9	0	9	0
11	[2, 3]	36	33	0	3
12	[1, 2]	87	28	0	59
12	[1, 3]	87	13	69	5
12	[2, 3]	278	251	0	27

all		3525	2093	575	857

Table 1. Open entries of γ_4 in KnotInfo 2026.10.5 and what the certificates give. "Settled": the value is now known; "lowered": the upper bound is lower.

corruption	rejected
other smoothing of the crossing	20 of 20
next crossing of the diagram	13 of 20
wrong target ($12a_1$)	20 of 20
bound lowered by one	20 of 20

Table 2. Corrupted certificates rejected by the verifier.

The remaining 1432 knots, listed in `still_open.json`, are not settled by one pinch move found in this way. For a knot with interval $[1, 2]$ that is not settled, no pinch move we tried gives a slice knot; this says nothing about whether $\gamma_4 = 1$.

Remark 4. The 465 Möbius bands found here are not in the data of Lee and Sabloff [8], whose search follows Dunfield and Gong [1] and runs over a finite family of bands chosen in advance. We have not determined which restriction of that family excludes them. The knots settled at $\gamma_4 = 2$ were outside their aim, which was Möbius bands; for them the target of the pinch move is a knot known to bound a Möbius band but not a disk.

Appendix A. The settled knots

$\gamma_4 = 1$ **(465 knots).**
